Abstract

Taking advantage of the chemical potential ($\mu_c$) of one and multi-layers of graphene nano-ribbons, we designed and analyzed the performance of plasmonic switches at mid-IR wavelengths. By slightly varying the chemical potential of graphene, significant resonance shift ($\Delta \lambda$) and modulation depth (MD) are achieved. Using the finite element method, our numerical simulations show that a plasmonic switch, made up of hexagonal boron nitride (hBN)/Graphene, has relatively large MD and wavelength shifts with N=6, and $\mu_c$ varying from 0.3eV to 0.4eV, 14 dB and 2.8µm. The proposed structure is useful for research on compact and largely tunable mid-infrared photonic devices in order to realize on-chip CMOS optoelectronic systems.
